# 1. Introduction

Embedded defects are unstable at zero temperature.

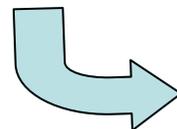

In the early universe, the finite temperature plasma existed.

They can be stabilized because of the asymmetry between **charged** and **neutral** scalar components.

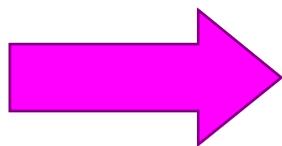

At the low temperature, the photon decoupling occurs.

Defects undergo core phase transition and/or decay.

**primordial magnetic field ?**

Some kinds of effects on cosmic microwave background radiation could be observed.

## 2. Cosmic String

$$\phi \equiv \phi_1 + i\phi_2 = \eta e^{in\theta}$$

string solution

$$G\mu = \left( \frac{\eta}{M_{pl}} \right)^2$$

is the parameter which determines the magnitude of the string effect.

$n$  : winding number

$$\mu \approx \eta^2$$

- line energy
- density of string

loop

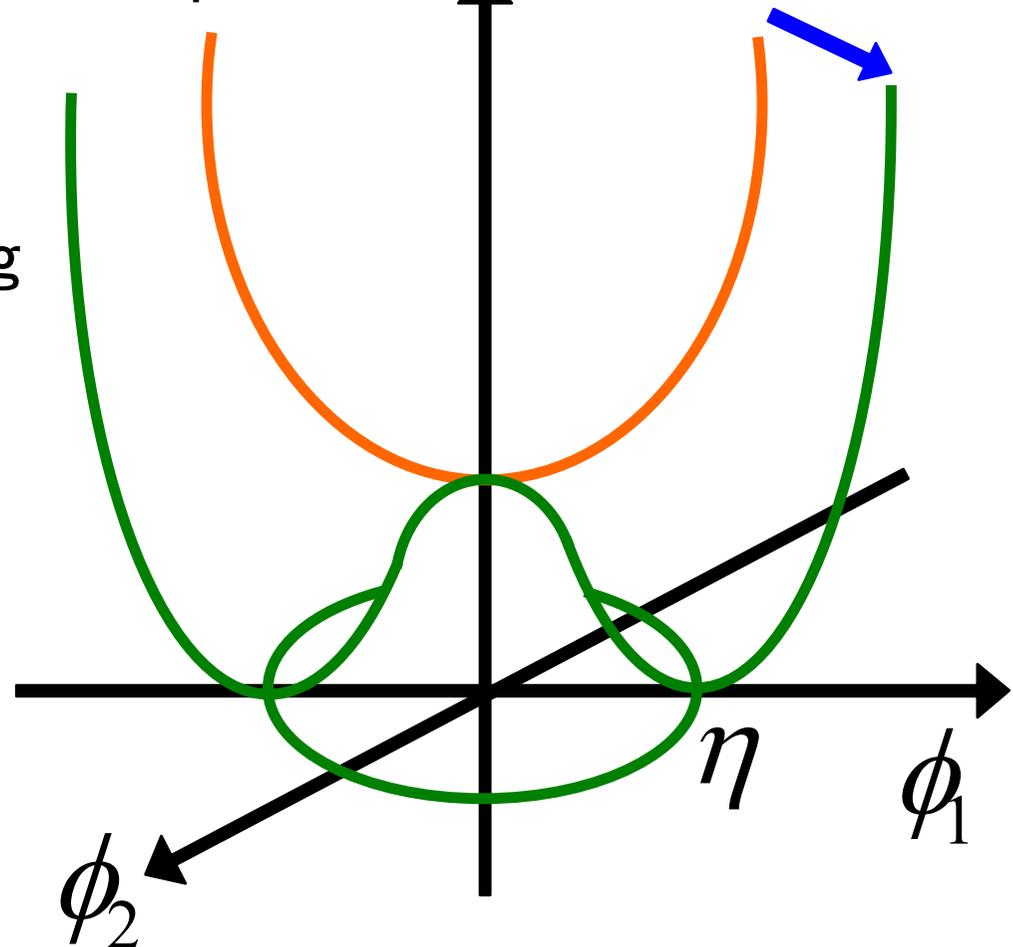

$$\langle \phi \rangle = 0$$

$2\pi n$

$$\langle \phi \rangle = \eta$$

effective potential phase transition

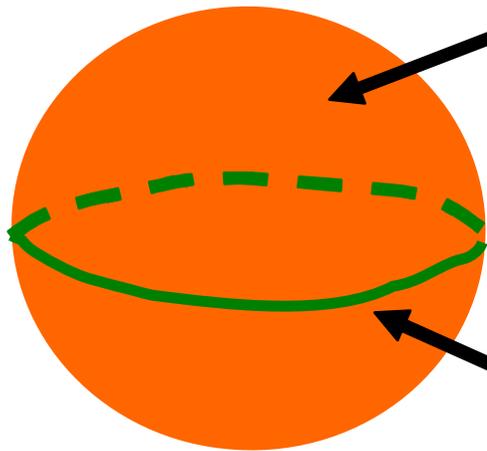

# 3. Embedded String

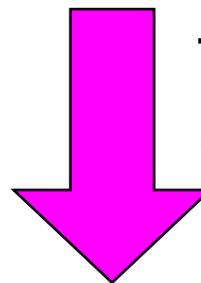

Although the configuration of embedded defects satisfies equations of motion, they are topologically, and in general also dynamically unstable.

ex.) three real scalar fields  $V(\phi) = \frac{\lambda}{4} \left( \sum_{i=1}^3 \phi_i^2 - \eta^2 \right)^2$

no string

$$S^2 : \sum_{i=1}^3 \phi_i^2 = \eta^2$$

freezing out  
certain components

$$(\phi_3 = 0)$$

$$S^1 : \sum_{i=1}^2 \phi_i^2 = \eta^2$$

string !

## 4. Pion String

one example of  
embedded **global** string

standard model of strong interaction

QCD phase transition ( $\cong 200$  MeV)

Below the confinement scale, this model is described by a sigma model involving the **sigma** field  $\sigma$  and the three **pions**  $\vec{\pi} = (\pi^0, \pi^1, \pi^2)$ .

$$L_0 = \frac{1}{2} \partial_\mu \sigma \partial^\mu \sigma + \frac{1}{2} \partial_\mu \vec{\pi} \partial^\mu \vec{\pi} - V_0 \quad V_0 \equiv \frac{\lambda}{4} (\sigma^2 + \vec{\pi}^2 - \eta^2)^2$$

cf. Although it is different from the cosmological scenario, following the Kibble–Zurek mechanism the pion strings are expected to be formed in LHC Pb – Pb collision experiments. These effects could be observable and bring distinction compared to conventional predictions.

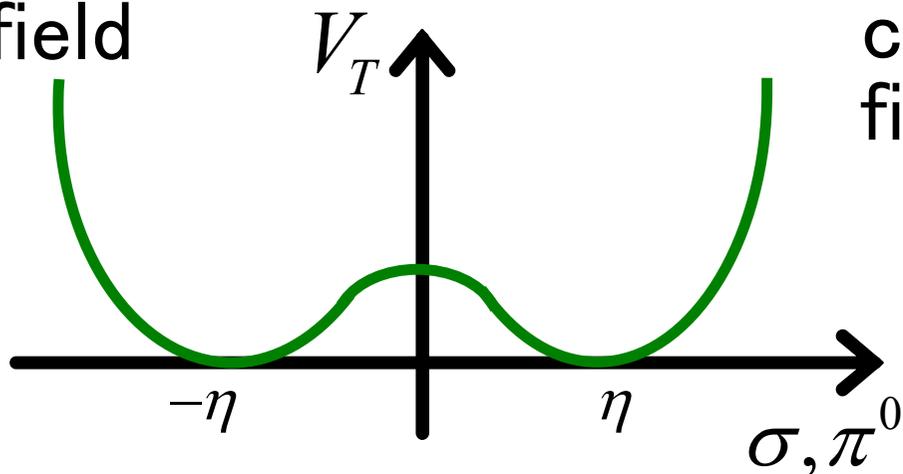

# 5. Finite Temperature Effect

When the background photon plasma can be regarded as a **thermal bath**, the interaction between charged fields and photon could be included into the **effective potential** as

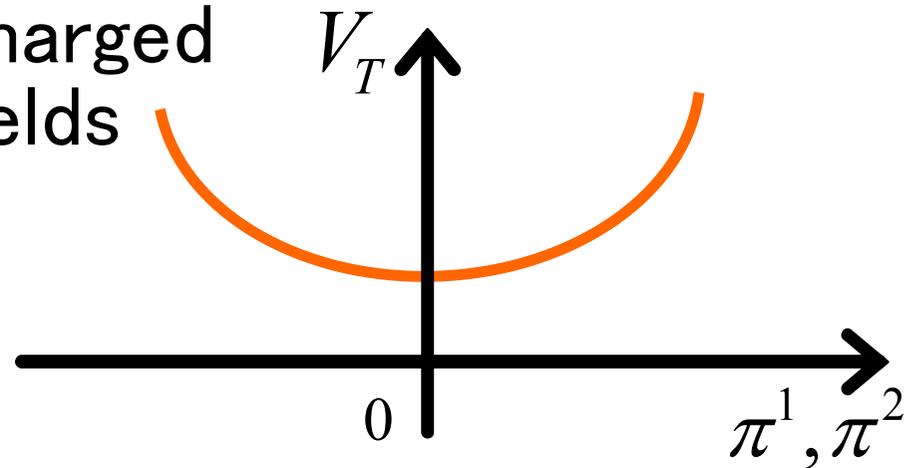

$$V_T = V_0 + \frac{1}{2} e^2 \kappa T^2 \{(\pi^1)^2 + (\pi^2)^2\} \quad . \quad \kappa \sim O(1)$$

Ref. MN & R. Brandenberger, 2003

neutral  
field

charged  
fields

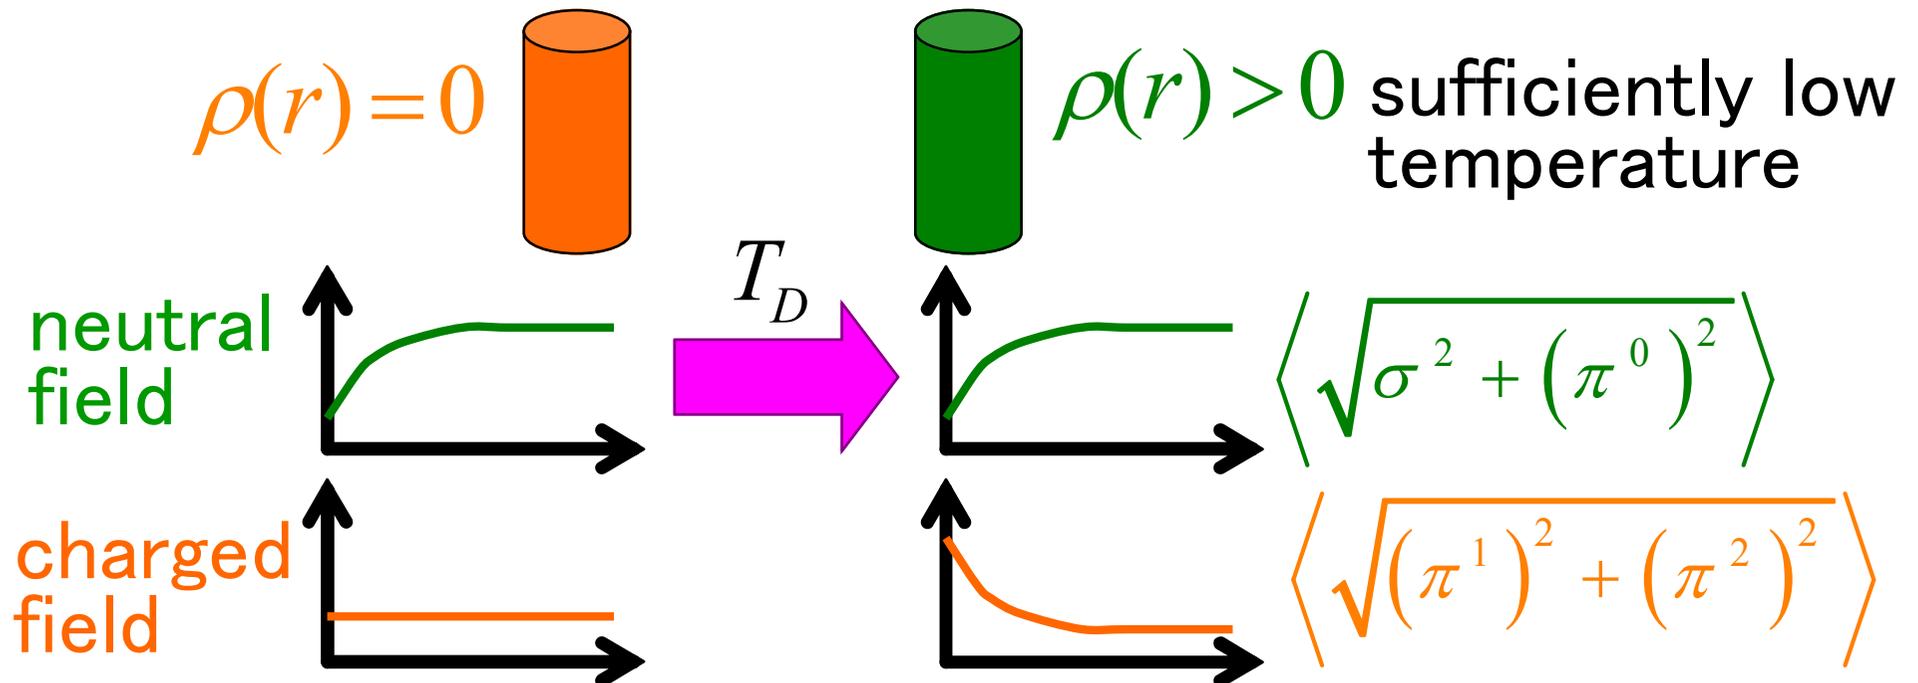

By analyzing the stability of the pion string solution under simple assumptions, the destabilization temperature can be calculated as  $T_D = 2\lambda^{1/2} \kappa^{-1/2} e^{-1} \eta$ .

# 6. Core Phase Transition

The results of numerical simulations show that even below  $T_D$ , the string does not decay. Actually the Higgs field has a finite expectation value at the string core and the neutral field configuration is not destroyed, which means that a core phase transition occurs.

finite temperature effect domination

- Since the winding number is a kind of topological charge, it must be conserved.

# 7. Superconductivity

After the core phase transition, charged fields have finite expectation value and the phase has a spatial gradient along the string so that the **electric current** will be generated.

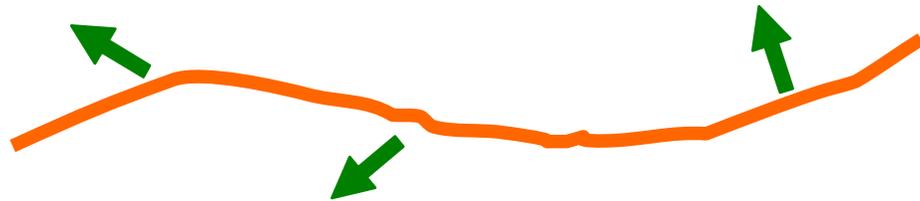

$$\sqrt{(\pi^1)^2 + (\pi^2)^2} = \phi_c(x, y) e^{i\varphi_c(z, t)}$$

current amplitude  $\sim e \frac{d\varphi_c}{dz}$

Davis & Shellard, 1989

loops  vorton

infinite strings

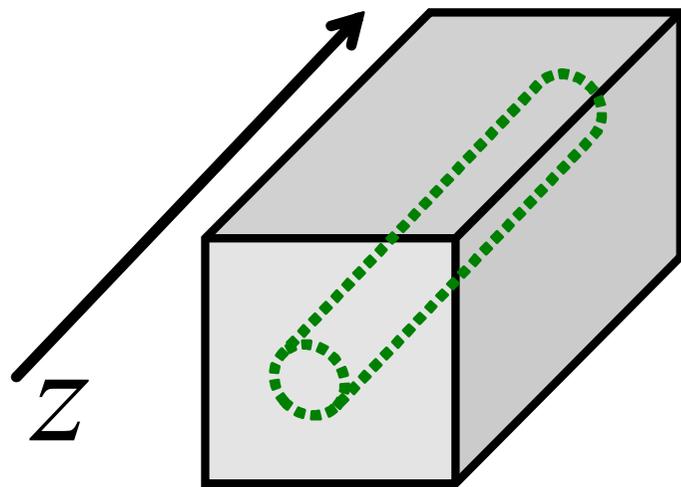

Infinitely long strings and/or loops of large curvature radius could show a filament-like spatial distribution feature.

 astrophysical counterparts: gravitational lensing?

# 8. 3-dimensional simulation

A initially translation symmetric string evolution is solved in a 3-dimensional box and the distribution of  $\varphi_c$  shows the winding number appears in some cases.

$300^2 \times 600$   
periodic boundary

The probability of winding number appearance is 20%.

$[-\pi, \pi]$  : random  
 $600\eta^{-1} / T^{-1}$  steps }  $\sim 16\%$

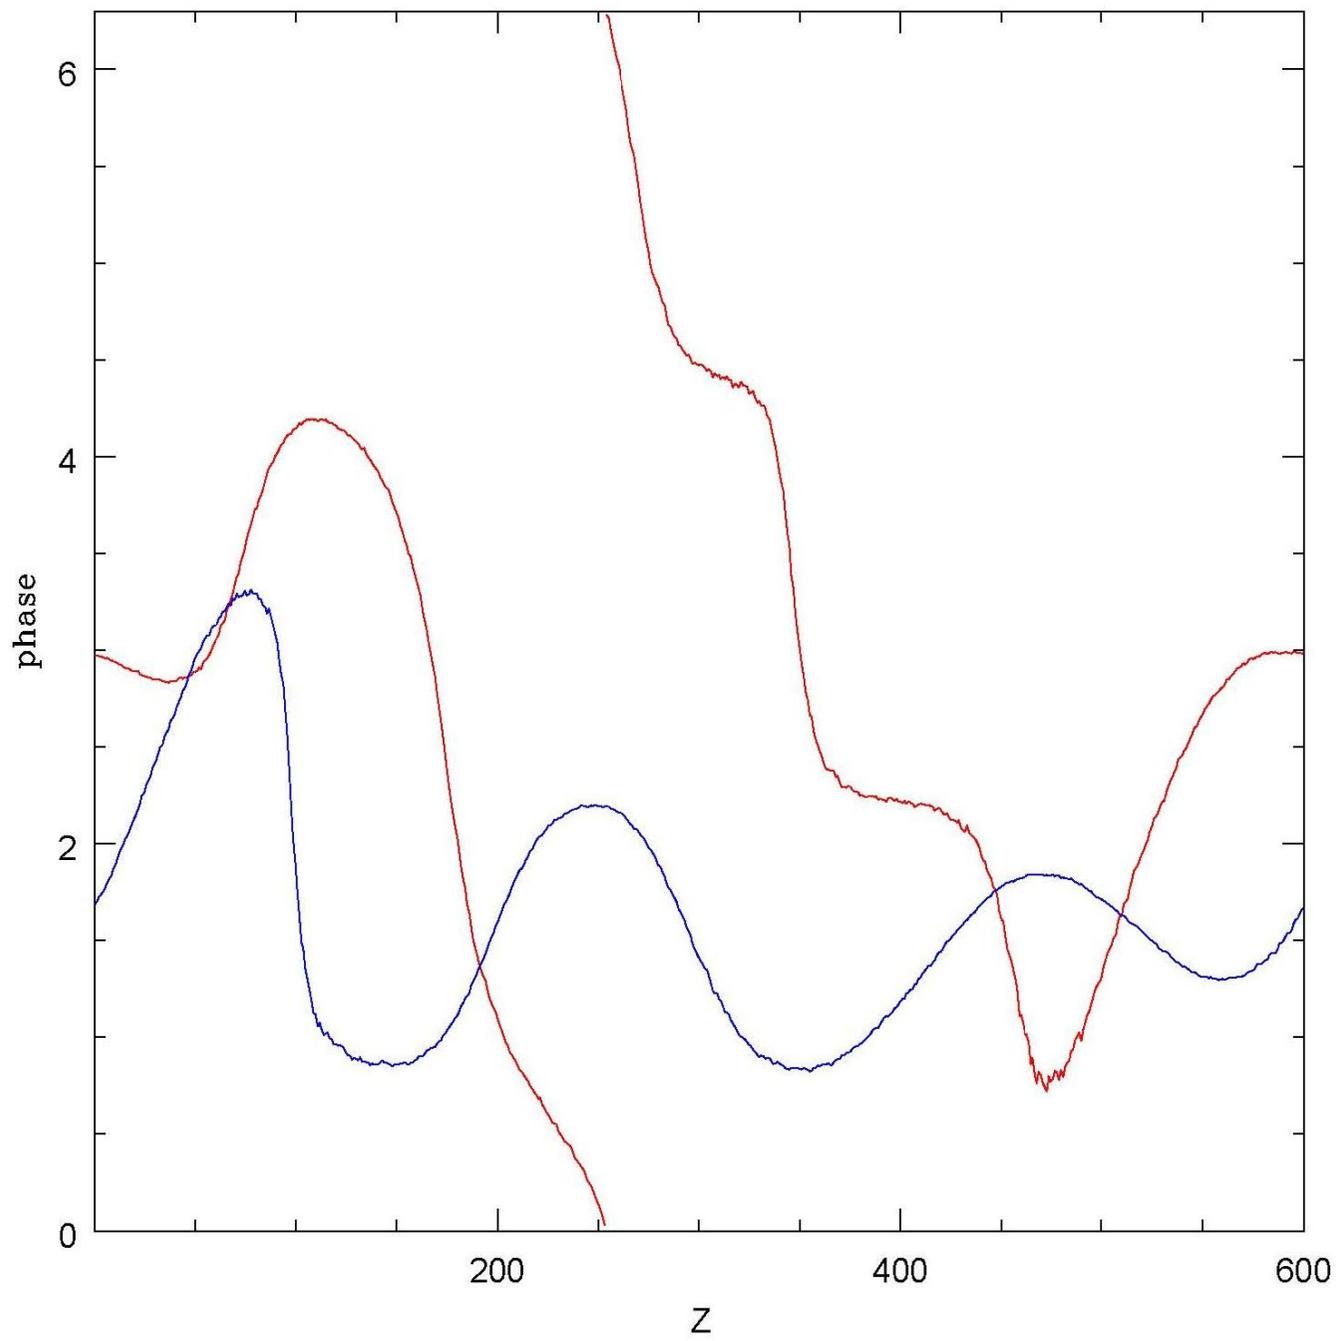

$$T = 10^{-2} \eta$$

$\varphi_c$  when the winding number exists.

$\varphi_c$  when there is no winding number.

# 9. Interaction of Scalar Field with Electromagnetic Field

In general, the following type of interaction between the electromagnetic field and a certain kind of field would appear in the Lagrangian when the anomaly or the Chern–Simons term is taken into account.

$$L = L_{EM} + L_{\text{int}} ; L_{\text{int}} = -\frac{1}{2} O_{\mu} A_{\nu} \varepsilon^{\mu\nu\alpha\beta} F_{\alpha\beta}$$

Then the equations of motion for electromagnetic field should be modified so that the generation of **magnetic field** and/or the **polarization** of background radiation would occur because of the field,  $O_{\mu}$ .

$$\partial_{\mu} F^{\mu\nu} = 4\pi J^{\nu} + O_{\mu} \varepsilon^{\mu\nu\alpha\beta} F_{\alpha\beta}$$

ex.) axion, type IIB string model...

# 10. Magnetic Field Generation from Pion Strings

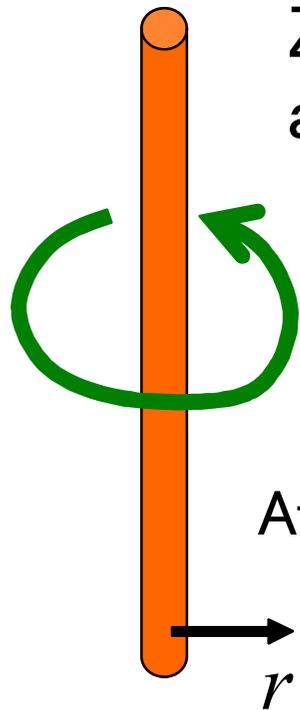

R. Brandenberger & X. Zhang, 1999

In case of the pion string, there exists an interaction between the pion field  $\pi^0$  and the electromagnetic field.

$$L_{\text{int}} = -\frac{N_c \alpha \pi^0}{24\pi f_\pi} \varepsilon^{\mu\nu\alpha\beta} F_{\mu\nu} F_{\alpha\beta} \quad N_c = 3$$

$\alpha$  : fine structure constant

Zero mode current appears within the string core and the azimuthal magnetic field is produced.

$$B_\theta = -N_c \frac{eT_C}{2\pi} \left( \frac{r}{\delta_s} \right)^{\alpha/\pi} \frac{1}{r} \quad \delta_s \approx f_\pi^{-1} \cdot \text{string core radius}$$

At the recombination,  $B(T_{\text{rec}}) \approx 10^{-23} \left( \frac{r}{\delta_s} \right)^{\alpha/\pi} \frac{1 \text{ kpc}}{r} \text{ G}.$

$T = T_C$  → present

# 11. Helicity of Magnetic Field

If the twist and tangle of strings are biased when the CP violation exists, then the **helicity** of magnetic field is also biased so that its conservation leads to the generation of larger **magnetic field** amplitude.

$$\text{helicity density : } \mathbf{H} = \frac{1}{V} \int_V d^3x \mathbf{A} \cdot \mathbf{B}$$

After the phase

transition,

$$\mathbf{H} \approx \varepsilon_{CP} 4N_c^2 \left( \frac{\xi_s}{T^{-1}} \right)^{-2+\alpha/\pi} \left( \frac{f_\pi}{T} \right)^{1+\alpha/\pi} T^3 .$$

$\varepsilon_{CP}$ : CP violation strength       $\xi_s$ : correlation length of strings

It can be shown that the helicity is not erased and according to the most optimistic estimation, on the scale of **1pc**, at the recombination,  $B \approx 10^{-9}$  G .

# 12. Modified Maxwell Equation

Next it is considered how the same interaction affects the light propagation.

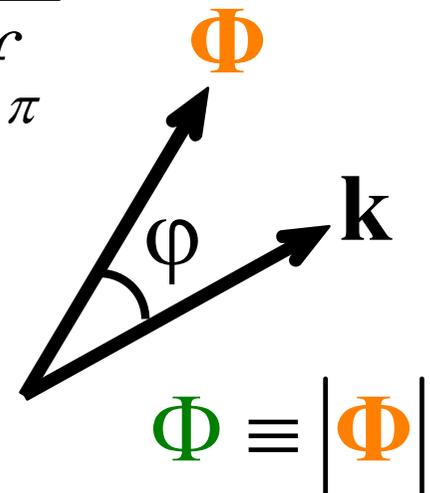

$$L_{\text{int}} = -\frac{N_c \alpha \pi^0}{24\pi f_\pi} \varepsilon^{\mu\nu\alpha\beta} F_{\mu\nu} F_{\alpha\beta}$$

If the time evolution of string distribution can be neglected, then the equations without the current under the string background will be written as

$$\begin{cases} \nabla \mathbf{E} = -\Phi \cdot \mathbf{B} \\ -\frac{\partial \mathbf{E}}{\partial t} + \nabla \times \mathbf{B} = \Phi \times \mathbf{E} \end{cases} \quad \Phi \equiv \frac{N_c \alpha}{3\pi} \nabla \frac{\pi^0}{f_\pi}$$

and the dispersion relation becomes

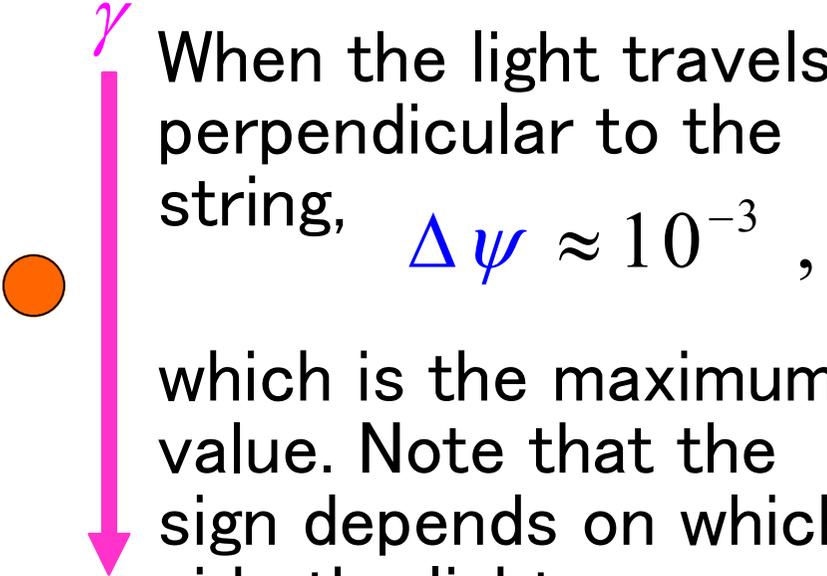

$$k^2 = \omega^2 \pm \omega \Phi \cos \varphi \left( 1 - \frac{\Phi^2 \sin^2 \varphi}{\omega^2 - k^2} \right)^{-1/2} .$$

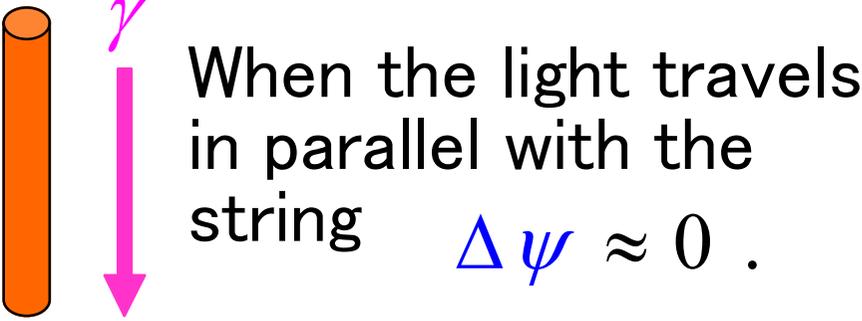

# 13. Rotation of Polarization Axis

Under the approximation that  $\Phi$  is sufficiently small,  $k \cong \omega \pm \frac{\Phi}{2} \cos \varphi$ .

Thus the rotation angle difference of polarization axis between left-handed polarization and right-handed one,  $\Delta\psi$ , can be estimated as follows dependent on the direction of the string axis to the line of sight.

 When the light travels perpendicular to the string,  $\Delta\psi \approx 10^{-3}$ , which is the maximum value. Note that the sign depends on which side the light passes.

 When the light travels in parallel with the string  $\Delta\psi \approx 0$ .

➤ In any cases, the distance between the string and the light path is not so significant.

# 14. Summary

It is considered that the magnetic field generation by pion strings produced at the QCD phase transition and the interaction of this magnetic field with the cosmic background radiation.

- **Magnetic field** strength generated by pion strings depends on the distance to the string axis and it is sufficiently high when the effective  $\alpha$  is large.
- In the case that the bulk helicity exists, although the amplitude of **magnetic field** would be enhanced, the correlation scale should be smaller.
- It is shown that the **rotation of light polarization axis** is caused by the string field and the spatial distribution of rotation angle directly traces the arrangement of the strings in our universe.
